

You are to scrape a website and create one dataframe that could be used for an analysis. You do not need to perform an analysis on this data set. The steps to scrape a website, as I see it at this point, are as follows. The previous two labs should provide more detail.

1. Create a pattern that matches incomplete links on a webpage of interest and complete the links as necessary.
2. Determine where to store downloaded data. Create the appropriate file paths in R and ensure the appropriate directories exist on your machine.
3. Download each complete link to an appropriate file path.
4. Unzip each downloaded file using `unzip`.
5. Read in the unzipped data files and stack them, such that each data set has a same-named column that makes it unique.
6. Profit.
